

A photograph of a forest with tall, thin trees and a dense undergrowth of ferns and other plants. A person wearing a red helmet and dark clothing is visible in the middle ground, working in the forest. The background is a bright, sunlit forest canopy.

# Responses to Variable-Density Thinning for Forest Restoration

**Lathrop P. Leonard,** California State Parks  
**John-Pascal Berrill & Christa M. Dagley,**  
Department of Forestry and Wildland Resources,  
Humboldt State University

# Treatments

- **High Density** – 4.9 x 4.9 m
- +/- 1.2 m
- Choose RW, minor conifers
- RW clumps = 1 tree
- Leave some brush,  
small trees

# Treatments

## **Low Density – 6.1 x 6.1 m**

# Treatments

## Localized Release

- Encouraging self-thinning

# Efficiency of Implementation

**Implementation rate:** hectares treated, per person, per day

- Localized Release = **0.79** ha/pp/day
- High Density (4.9 x 4.9 m) = **0.56** ha/pp/day
- Low Density (6.1 x 6.1 m) = **0.53** ha/pp/day

**Mill Creek  
Forest Restoration  
2003-2016**

# Experimental Design

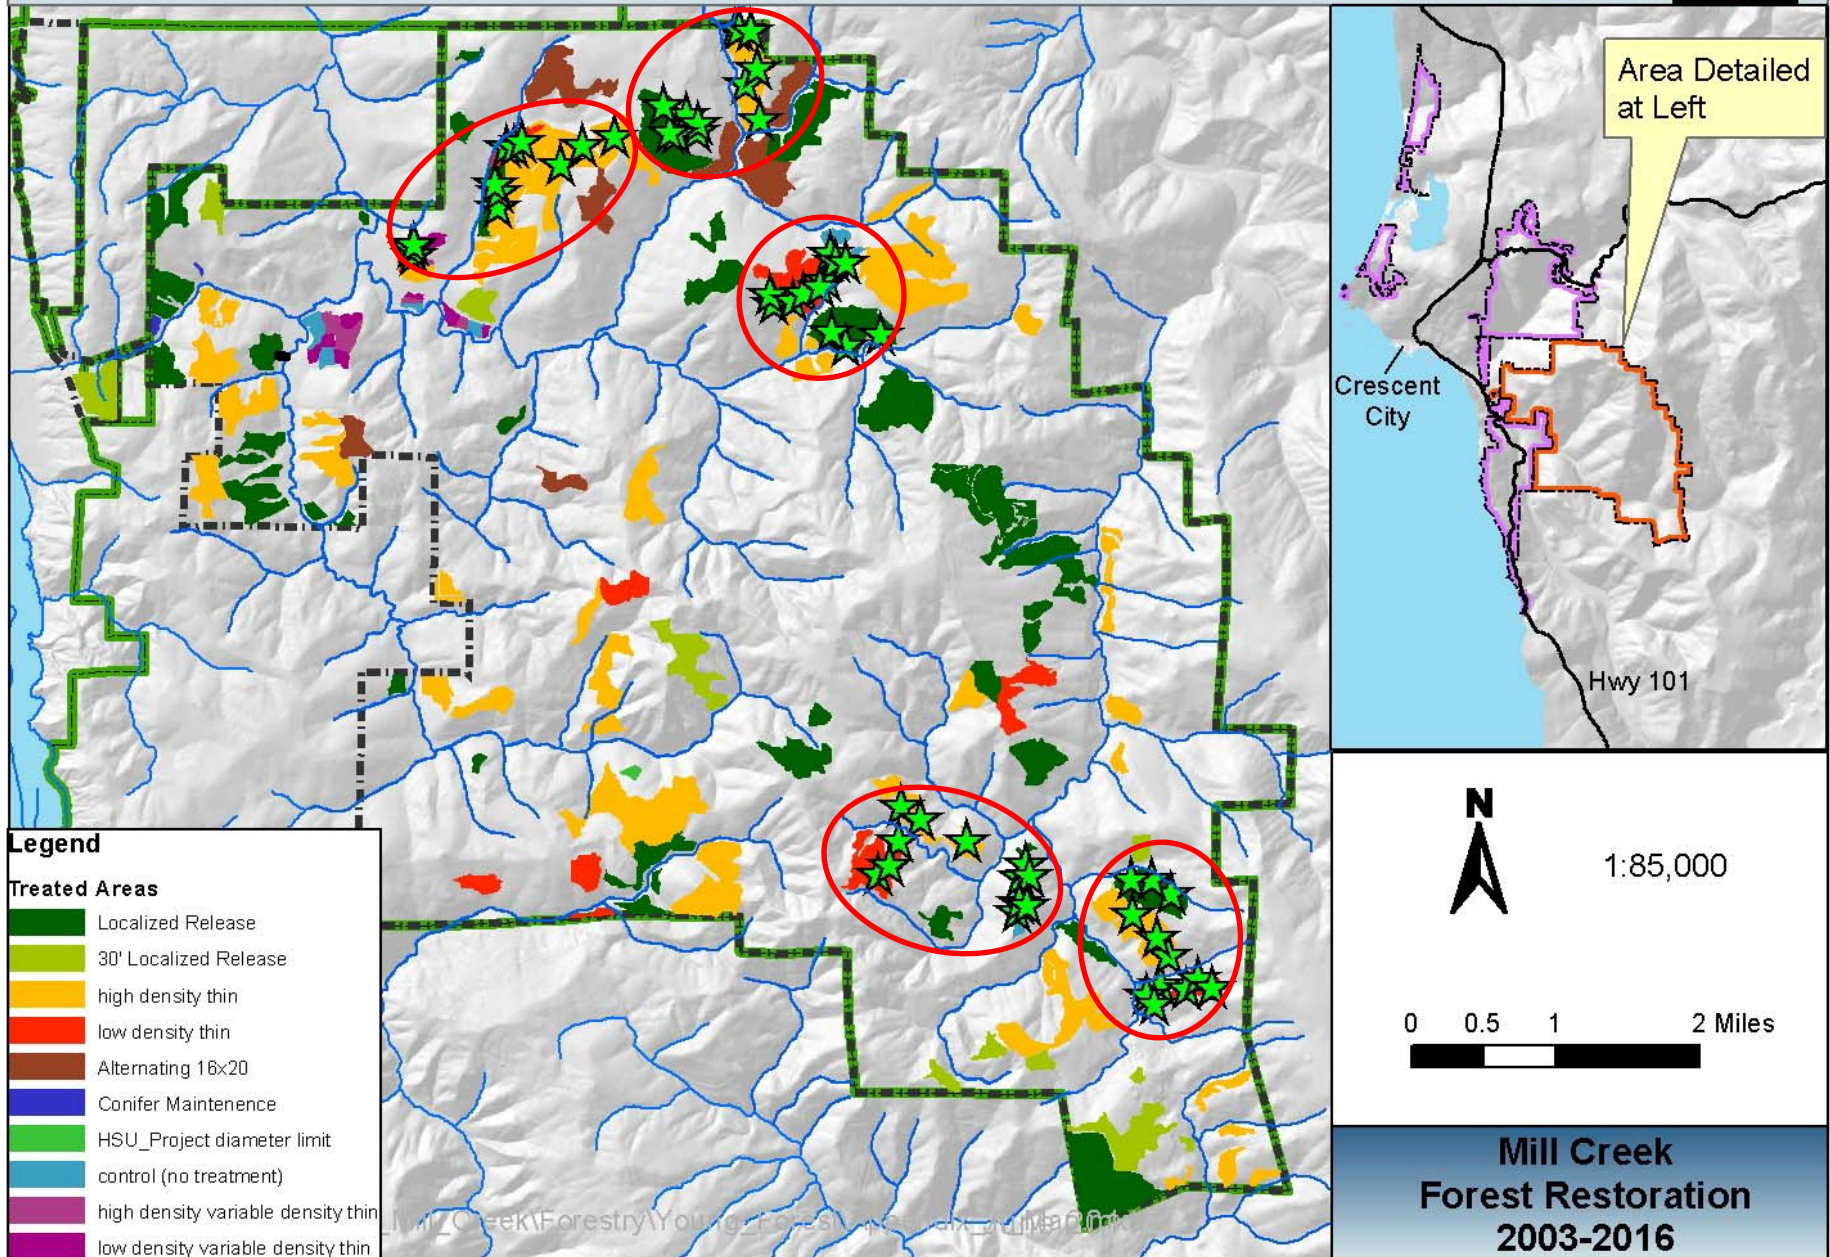

- Treatments randomly assigned within blocks (except some controls)
- 3 plots / treatment area
- 5 replicates (blocks) = 60 plots
- Plots established after treatment (Year 0), re-assessed after four years (Year 4)

North Coast Redwood District

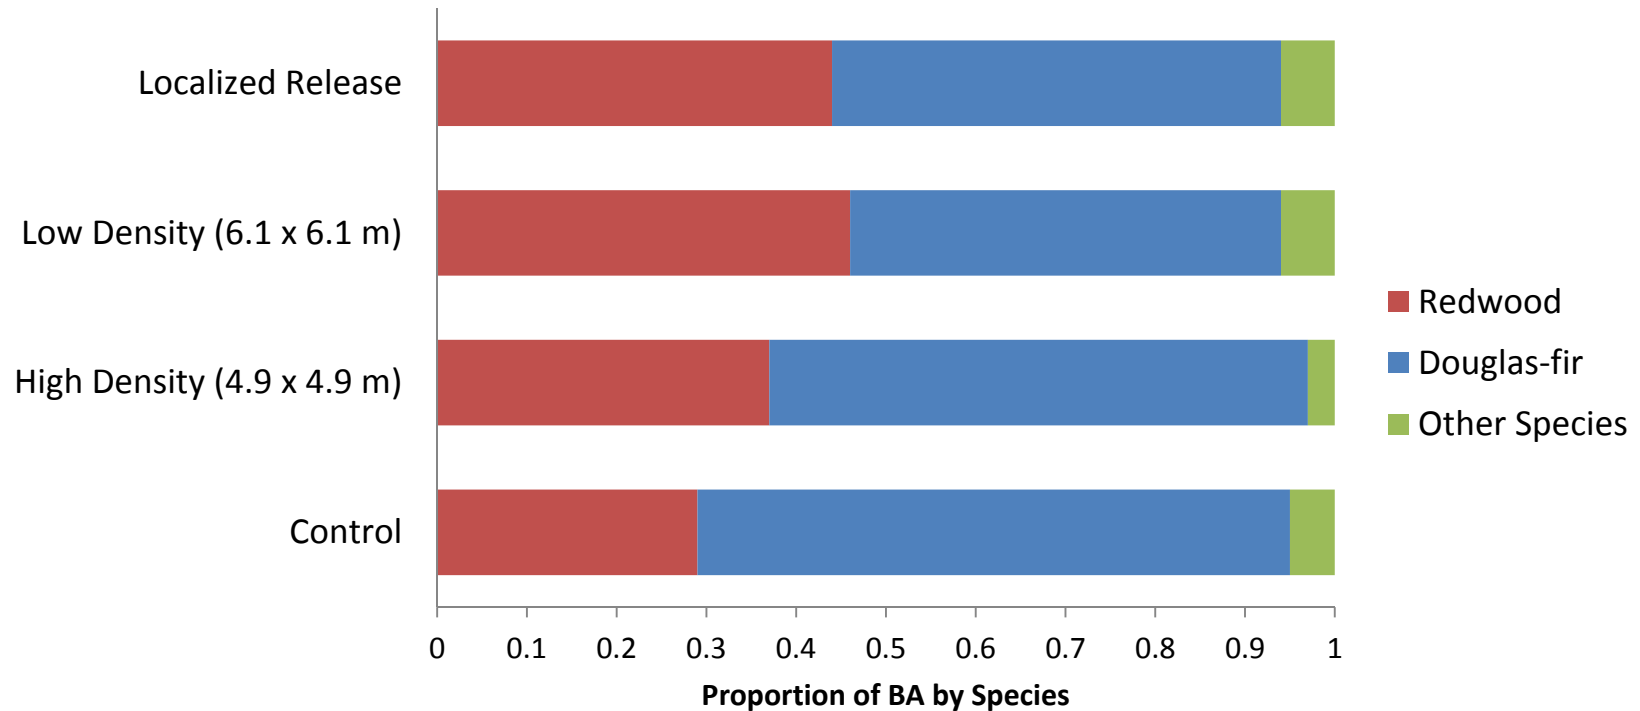

# Research Questions

After VDT treatments,

- How did treatments alter
    - tree species composition?
    - stand density & structural diversity?
  - How fast did trees grow?
  - How many trees sustained bear damage?
  - How deep was slash (fuels) and did it change?
- (+ planned work: understory light & vegetation; diversity index)

# Species Composition

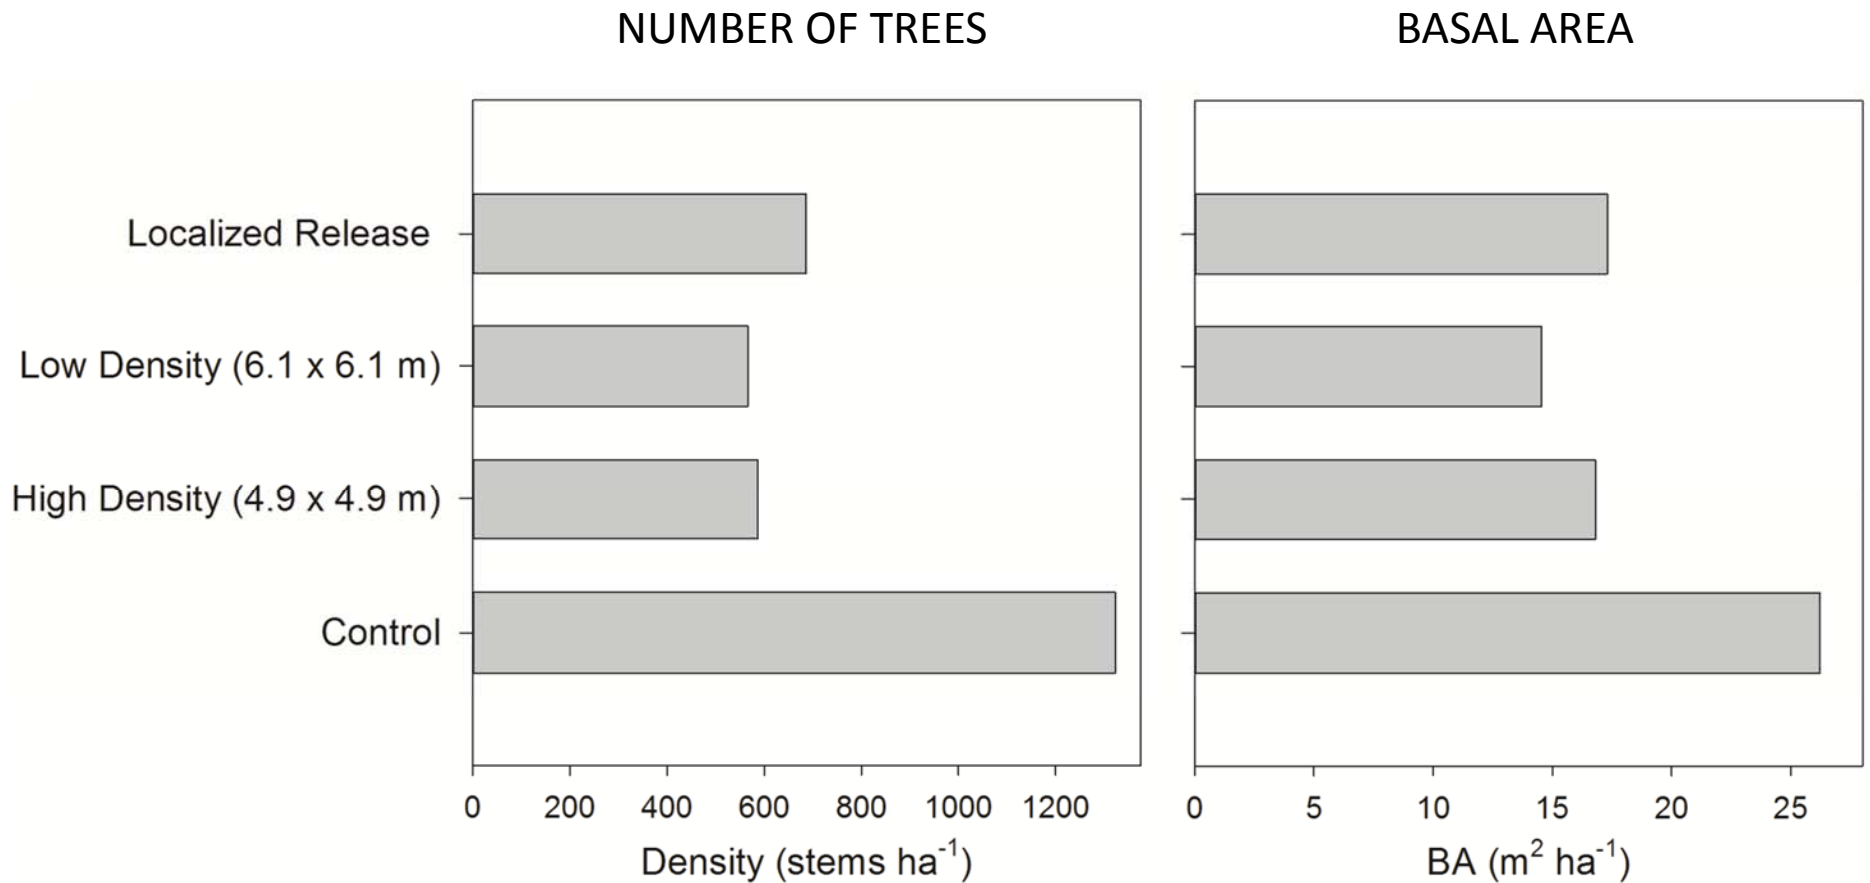

Low density thinning best promoted redwood  
and reduced Douglas-fir

# Stand Density

Low density thinning most reduced tree numbers and basal area

# Bear Damage in Redwood & Douglas-fir

- Bears prefer redwoods
- Thinning leads to damage

# Redwood Tree Size

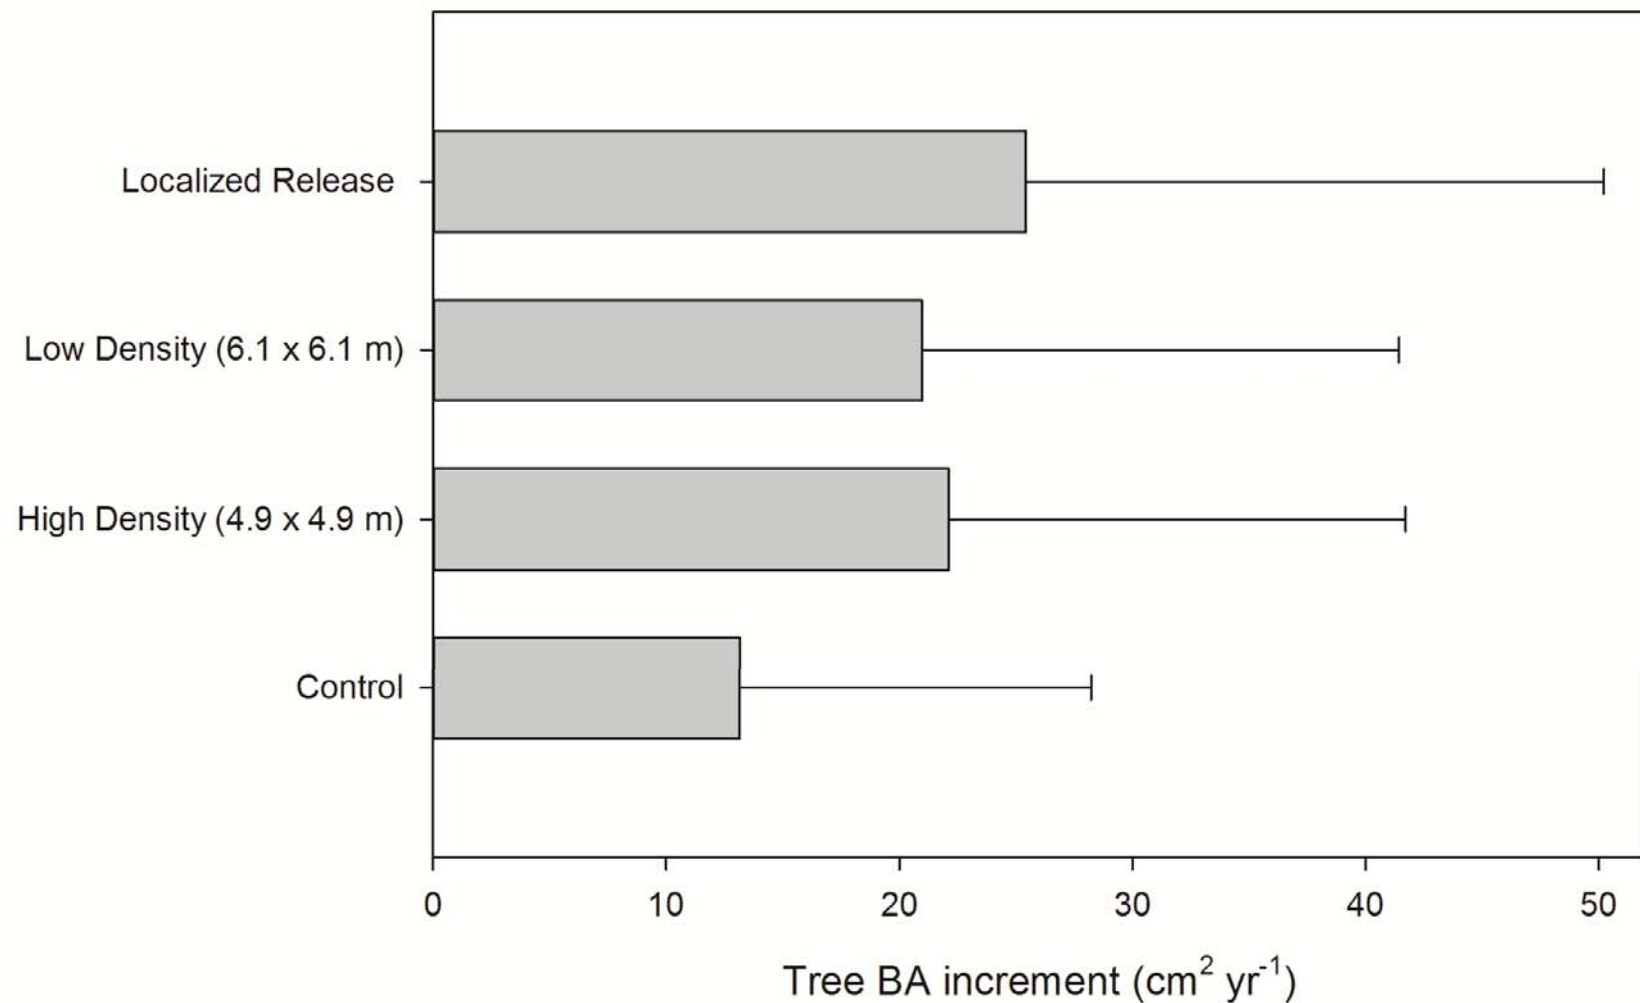

**Average size of undamaged redwood** was slightly larger and more variable after localized release and high density thin

# Undamaged Redwood Growth Rates

Tree BA increment was greatest, more variable for localized release

# Dominant Tree Growth Rates

Diameter growth of largest 100 stems/ha (40 tpa) assumed to represent restored old-growth overstory (i.e., 50 largest RW & 50 largest DF/ha)

Localized release: favors RW while restricting DF

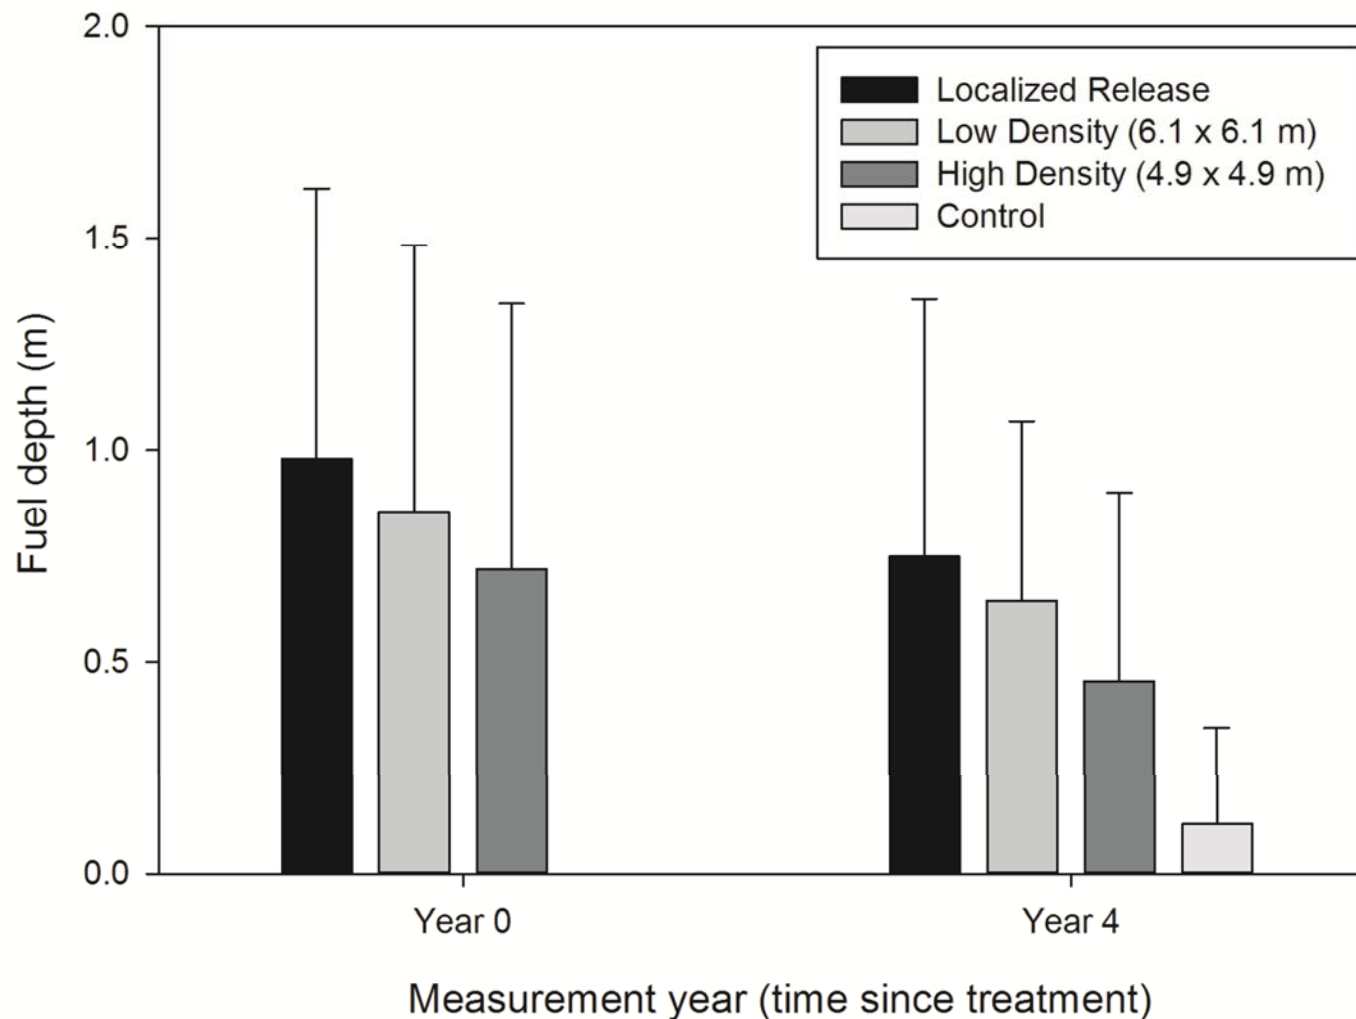

# Slash Depth

# Slash (Fuel Bed) Depth

- Slash depth highly variable across each treatment

# Summary

As a result of VDT treatments,

- slash (fuel bed) deepest:  $LR > LDT > HDT \gg \text{Control}$   
(but dense Controls are also a fire hazard)
- bear damage among redwoods:  $LR \approx LDT > HDT \gg \text{Control}$   
(good or bad for restoration objectives?)
- bear damage among Douglas-fir:  $LDT > LR \approx HDT \gg \text{Control}$   
(good or bad for restoration objectives?)

# Summary

As a result of VDT treatments,

- composition shift towards redwood:

**LDT** > LR > HDT

- structural diversity:

**LR** > LDT  $\approx$  HDT > Control

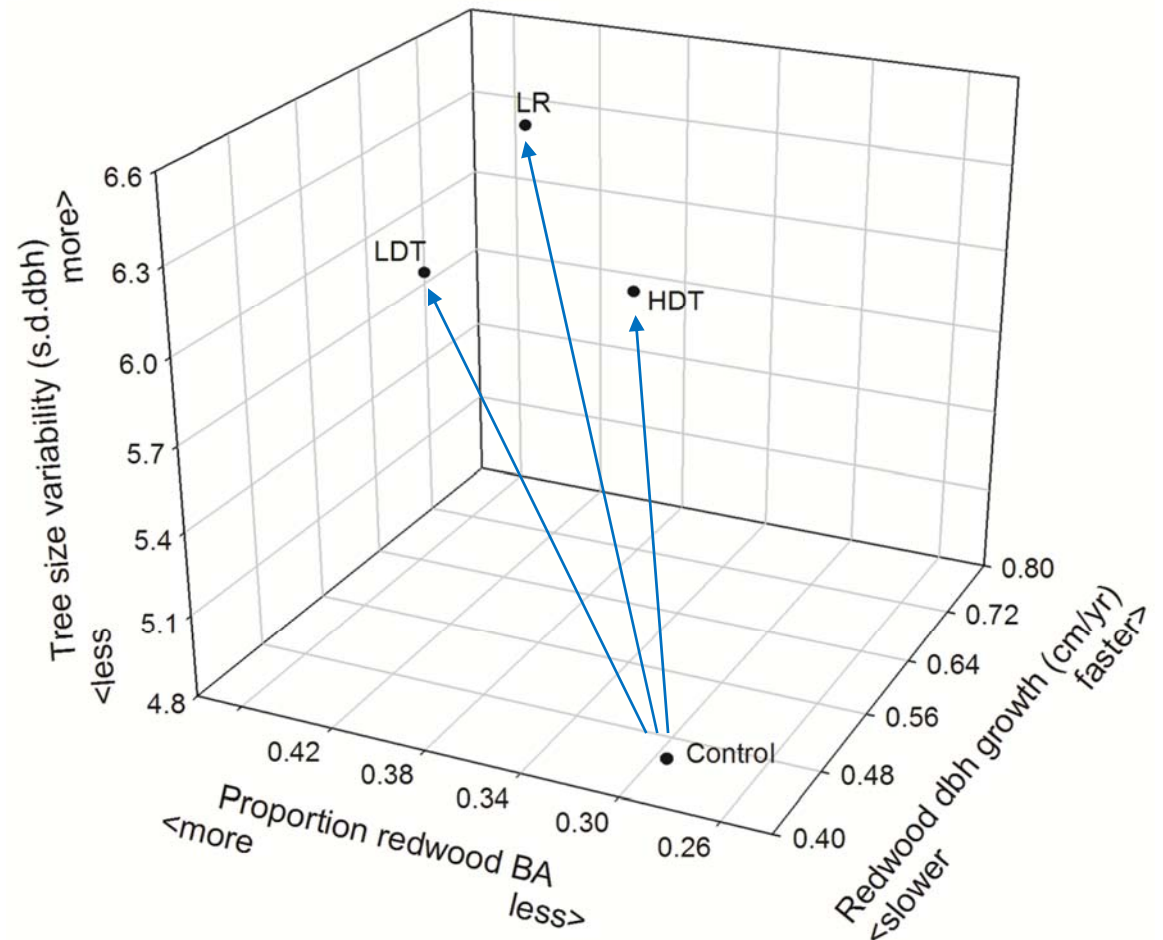

- redwood dbh growth:

**LR** > LDT  $\approx$  HDT > Control

- efficiency

**LR** > HDT > LDT

Creating complexity isn't  
always expensive
